### Dense core chemistry as seen by Herschel, NOEMA and ALMA

Sébastien Maret

Institut de Planétologie et d'Astrophysique de Grenoble

### The formation of a star

Molecular cloud

Prestellar

Protostar Outflows and disk

Main sequence star with planets

### The formation of a star

Molecular cloud  $n({
m H}_2) \sim 10^3 {
m cm}^{-3}$  $T \sim 10 {
m K}$ 

Prestellar core

Protostar Outflows and disk

Main sequence star with planets

 $n(\mathrm{H}_2) \sim 10^7 \,\mathrm{cm}^{-3}$  $T \gtrsim 100 \mathrm{K}$ 

### The formation of a star

Main sequence star with planets

The gas composition is altered significantly (e.g. freeze-out, ices evaporation...)

# Why study chemistry?

- Chemistry and the physics of the star formation process are coupled (gas temperature, ionization fraction...)
- Molecular lines can be used as probes of the gas physical conditions (temperature, density, gas velocity)
- Planetary system may inherit of some of the species that are formed during the early phases

### In this talk...

- I will the review the recent progress in our understanding of the dense core chemistry
- I will also present a few results on the chemistry in embedded (Class 0) protostars obtained with NOEMA
- I will discuss some perspectives for the study of dense core chemistry with ALMA and NOEMA

### Physical conditions in cores

 Density in the cloud determined from the extinction of background stars

Alves et al. (2001)

#### Nielbock et al. (2012)

• At the core center:

 $T_{\rm dust} \simeq 8 \,{\rm K}$ 

$$n({\rm H}_2) = 3 \times 10^5 {\rm cm}^{-3}$$

20azimuthally averaged 18 azimuthally averaged,  $n_{\rm H} \ge 6 \times 10^2 \text{ cm}^{-3}$ 0 Dust temperature [K] 16 - best ray-tracing fit 14 12 **- -**E 10 -SE --W Volume density [cm<sup>-3</sup>] 10  $\propto r^{-2}$  $10^{4}$ 103 .... - best ray-tracing fit 10 100 Radius ["]

## Freeze-out on grains

• Depletion timescale (Tielens et al. 1982):

$$\tau_{\rm dep} = (\sigma_{\rm gr} v S n_{\rm gr})^{-1}$$

• Typical grain radius:  $0.1\,\mu{
m m}$ 

$$\tau_{\rm dep} = \frac{10^9}{n({\rm H}_2)} \,\mathrm{yr}$$

• B68 :  $n(H_2) = 3 \times 10^5 \text{ cm}^{-3}$  $\tau_{\text{dep}} = 3000 \text{ yr}$  • Thermal desorption:

$$\tau_{\rm des} = \left(10^{12} \, e^{\frac{-E_{\rm b}}{kT_{\rm dust}}}\right)^{-1} \, s$$

- Binding energy:  $E_{\rm b} \sim 1000-2000\,{\rm K}$
- At 10 K, thermal desorption is extremely slow
- Non-thermal desorption processes exist, e.g. cosmic rays photodesorption

#### Bergin & Tafalla (2007)

Maret, Bergin & Tafalla (2013)

- The H<sup>13</sup>CO<sup>+</sup> (1-0) line observations and models indicate:
  - Cosmic-ray photodesorption (CRP)
  - Grain growth at the core center

Maret, Bergin & Tafalla (2013)

## Deuterium fractionation

Deuterium fractionation:

$$\mathrm{H}_{3}^{+} + \mathrm{HD} \rightleftharpoons \mathrm{H}_{2}\mathrm{D}^{+} + \mathrm{H}_{2}$$

The reverse reaction has an activation barrier of  $\sim$  200 K, so the reaction is irreversible at 10 K:

$$\mathrm{H}_3^+ + \mathrm{HD} \to \mathrm{H}_2\mathrm{D}^+ + \mathrm{H}_2$$

At low temperature:

• H<sub>2</sub>D+ can itself react with HD:

### $H_2D^+ + HD \rightarrow D_2H^+ + H_2$

- Deuterium is then transferred to ions, e.g. DCO+, N<sub>2</sub>D+, etc...
- CO is the major destroyer of H<sub>2</sub>D+ and therefore the H<sub>2</sub>D+ abundance increases as CO freezesout

#### Parise et al. (2011)

### Proto-stellar phase

Major Gas-Phase Tracers in Protostars

![](_page_26_Figure_2.jpeg)

### Conclusions

- Dense core chemistry is characterized by:
  - The freeze-out of heavy species (CO, H<sub>2</sub>O, etc.)
  - Large deuteration fractionation (H<sub>2</sub>D<sup>+</sup>, D<sub>2</sub>H<sup>+</sup>)
  - Growing evidence of the important role of secondary UV photons (desorption, COM formation)
- Class 0 protostar chemistry is dominated by the thermal evaporation of CO and H<sub>2</sub>O ices
- Important progresses expected in the coming years as ALMA and NOEMA ramp up to their full capacities

### Perspectives

- ALMA will allow to make high resolutions images of several tracers (H<sub>2</sub>D+, D<sub>2</sub>H+) to study the chemistry/physical conditions on the small scales (or in more distant cores)
- NOEMA is also well suited to study cores; its large instantaneous bandwidth (16 GHz) and dual band capability should allow for an inventory of species (e.g. COMs) in cores
